PHP Security - How to secure an intranet project I have been tasked with maintaining a PHP project that was originally created by another programmer. I am not familiar with PHP and the application is already running but our company is currently requesting that all content be moved to a new database. There are about 20 projects that need to be migrated and as I read through each project it seems like they are all using the same mysql credentials

and as a result I am thinking it would be possible for someone to change the "config" file and make new accounts that can access all the projects. Is there any type of security that would stop this from happening? In addition is there any resources you could point me to that would explain the process of securing a PHP intranet application? A: It's always a risk to assume that it's just a matter of changing the configuration. I have found that unless the config is really tight, which it almost never is, that it's the source code and the methods that execute that are important. To get that tight, you can do one of two things: Write methods with SecurityManager and check that they're not executed when an action's security is set to anything other than public. Use composer, or another PEAR package, and use it to write methods that validate the security of actions. The most secure way is probably going to be the second. You should use composer or PEAR only if you're comfortable doing it. I can't help but think that by the time you've been hired to do this work, you'll have been asked to write your own code. In which case, this might be a good time to learn how to write secure code. You could write a PEAR package that does an actions security check before running the action, which would likely be a really bad idea, but it might work. The Rangers are continuing to bring in prospects to fill in as 82157476af
